Loading files (Colab, Google Drive), loading data (readlines, numpy), and an intro to plotting (matplotlib)

ESS 116 | Fall 2024

Prof. Henri Drake, Prof. Jane Baldwin, and Prof. Michael Pritchard

(Modified from Ethan Campbell and Katy Christensen's materials for UW's Ocean 215)

What we'll cover in this lesson

1. Loading and saving files to Google Colab

2. Loading data using readlines and numpy

What we'll cover in this lesson

1. **Loading and saving files to Google Colab**

2. Loading data using readlines and numpy

Real data

We could keep creating simple arrays...

```
np.array([[1,2,3,4],[5,6,7,8]])
```

But looking at real data is usually more interesting!
(and kind of the point of data science)

Using real data means having data files

Assignment #2, Q4 - data numpy array

```
# Data in this array consists of 4 columns:
# Latitude, longitude, T at 5 m (˚C), T at 11 m (˚C)

T_data = np.array([[51.7439,2.4476,14.726,14.736],[51.7147,2.4071,14.746,14.756],[51.6851,2.3664,14.796,14.816],[51.6561,2.3254,14.856,14.866],
  [51.627,2.2854,14.866,14.876],[51.5981,2.2454,14.896,14.916],[51.5689,2.2055,14.936,14.946],[51.5404,2.1661,14.946,14.956],
  [51.5122,2.127,14.936,14.946],[51.4831,2.087,14.956,14.966],[51.4545,2.0478,15.016,15.026],[51.4271,2.01,15.106,15.116],
  [51.3959,1.9686,15.136,15.146],[51.3635,1.9252,15.086,15.086],[51.3304,1.8848,14.826,14.826],[51.2986,1.8437,14.616,14.626],
  [51.2679,1.8036,14.527,14.547],[51.2371,1.7642,14.636,14.646],[51.207,1.7255,14.666,14.686],[51.1782,1.6886,14.766,14.786],
  [51.1497,1.6519,14.736,14.756],[51.1215,1.6156,14.716,14.726],[51.0984,1.581,14.656,14.666],[51.077,1.5485,14.567,14.577],
  [51.0586,1.5198,14.467,14.477],[51.0354,1.4841,14.247,14.257],[51.0088,1.4431,14.117,14.147],[50.9829,1.4033,14.307,14.327],
  [50.957,1.3635,14.337,14.347],[50.9314,1.324,14.307,14.327],[50.9077,1.2801,14.327,14.337],[50.8867,1.2301,14.207,14.217],
  [50.8654,1.1789,14.157,14.177],[50.8436,1.1266,14.167,14.187],[50.8213,1.0736,14.137,14.157],[50.7988,1.0196,14.257,14.277],

  [50.454,-0.2916,15.376,15.386],[50.4426,-0.35                ],[50.4313,-0.1                6],[50.4168,-0.4275,15.456,15.466],
  [50.409,-0.4882,15.436,15.446],[50.4017,-0.547                76],[50.3933,-0.60                26],[50.3796,-0.6583,15.396,15.406],
  [50.3668,-0.7114,15.396,15.406],[50.3524,-0.763,1                .406],[50.3396,-0.8151,                .406],[50.3288,-0.8668,15.476,15.486],
  [50.3223,-0.9188,15.556,15.566],[50.316,-0.97,15.61                .636],[50.3092,-1.0191,15.6                .706],[50.3024,-1.0675,15.746,15.756]])

```

Instead of having the data hard-coded into your notebooks, we will now learn how to read data files

Using real data means having data files

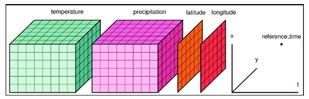
Most common data file types

Covered in this class

.txt (ASCII text)

.csv (comma separated values)

.xlsx (Microsoft Excel)



.nc (NetCDF)

Not covered in this class (probably)

.json (JavaScript object notation)

.jpg (JPEG)

.avi (audio-visual interleave)

Using data files in Colab notebooks

Google Colab runs on the Cloud so files that are stored on your computer (locally) are not accessible. There are options for loading data files:

1) Mount your Google Drive

Pros:
- Your data files are accessible from any machine, every time you open the notebook because the are on Drive
- Is good for sharing data and code with others

Cons:
- Have to upload files to Cloud and navigate Google Drive file structure
- Requires internet to even look at the data

2) Upload local files to a runtime

Pros:
- Can keep your files offline/doesn't take space on Google drive
- Is good for a fast look at a file to see what is in it

Cons:
- Removes access files after your runtime is over (sometimes)
- Manually uploading files every time you re-open the notebook can take a lot of time

Using data files in Colab notebooks

Google Colab runs on the Cloud so files that are stored on your computer (locally) are not accessible. There are options for loading data files:

1) Mount your Google Drive

Pros:
- Your data files are accessible from any machine, every time you open the notebook because the are on Drive
- Is good for sharing data and code with others

Cons:
- Have to upload files to Cloud and navigate Google Drive file structure
- Requires internet to even look at the data

2) Upload local files to a runtime

Pros:
- Can keep your files offline/doesn't take space on Google drive
- Is good for a fast look at a file to see what is in it

Cons:
- Removes access files after your runtime is over (sometimes)
- Manually uploading files every time you re-open the notebook can take a lot of time

We recommend mounting your google drive.

Mount your Google Drive to Colab (code)

```
1 from google.colab import drive
2 drive.mount('/content/drive')
```

```
Go to this URL in a browser: https://accounts.google.com/o/oa…

Enter your authorization code:
```

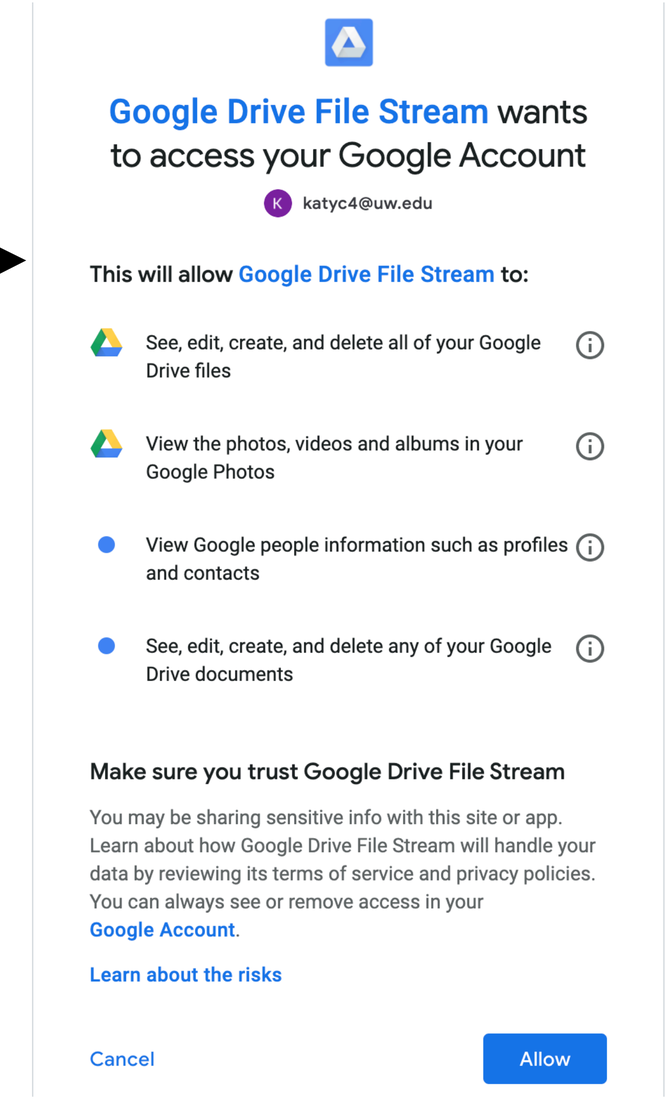
Mount your Google Drive to Colab (code)

```
1 from google.colab import drive
2 drive.mount('/content/drive')
```

```
Go to this URL in a browser: https://accounts.google.com/o/oa

Enter your authorization code:
```

Click the link that appears after running the cell, a new tab will open



Mount your Google Drive to Colab (code)

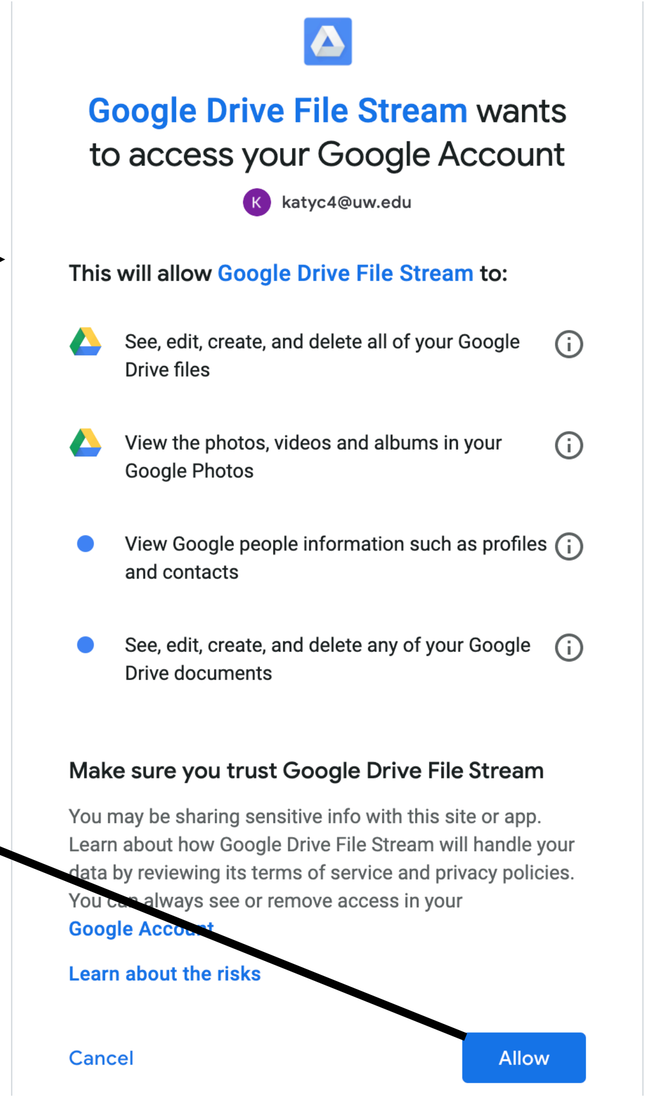
```
1 from google.colab import drive
2 drive.mount('/content/drive')
```

```
Go to this URL in a browser: https://accounts.google.com/o/oa

Enter your authorization code:
```

Click the link that appears after running the cell, a new tab will open

Clicking **Allow** brings you to a new page with an authorization code.
Copy and past it into the notebook.



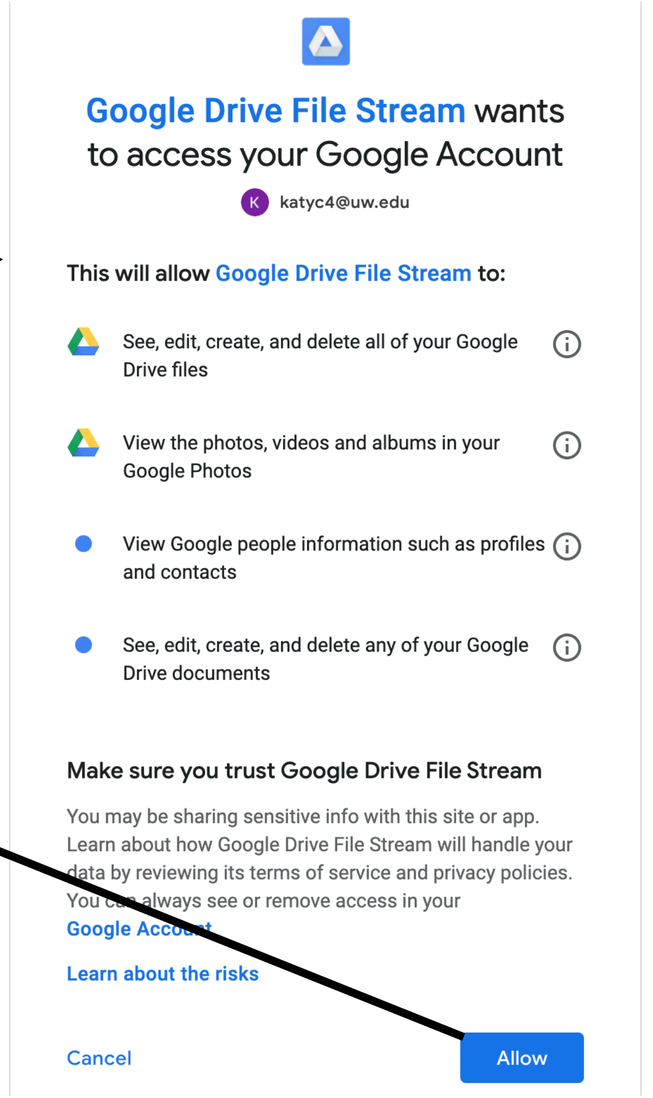
Mount your Google Drive to Colab (code)

```
1 from google.colab import drive
2 drive.mount('/content/drive')
```

```
Go to this URL in a browser: https://accounts.google.com/o/oa

Enter your authorization code:
```

Click the link that appears after running the cell, a new tab will open



Clicking **Allow** brings you to a new page with an authorization code.
Copy and past it into the notebook.

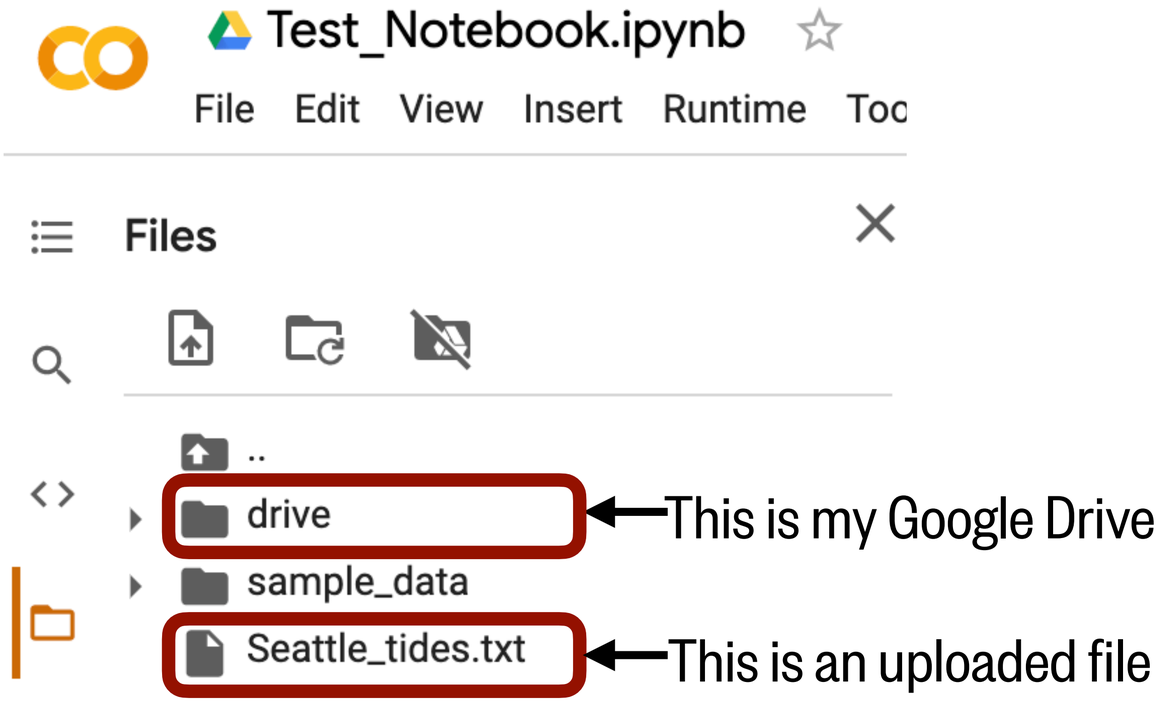
Load the data from the files into Python here!

Un-mounting the Google Drive once you have loaded your data is preferred.

```
1 drive.flush_and_unmount()
```

A note about file paths

After mounting your drive or uploading your files, they should appear in your sidebar for **Files**



When you want to access those files (to load their data), you will use its **path**

Path for uploaded files:
a string containing the file name

```
filepath = 'Seattle_tides.txt'
```

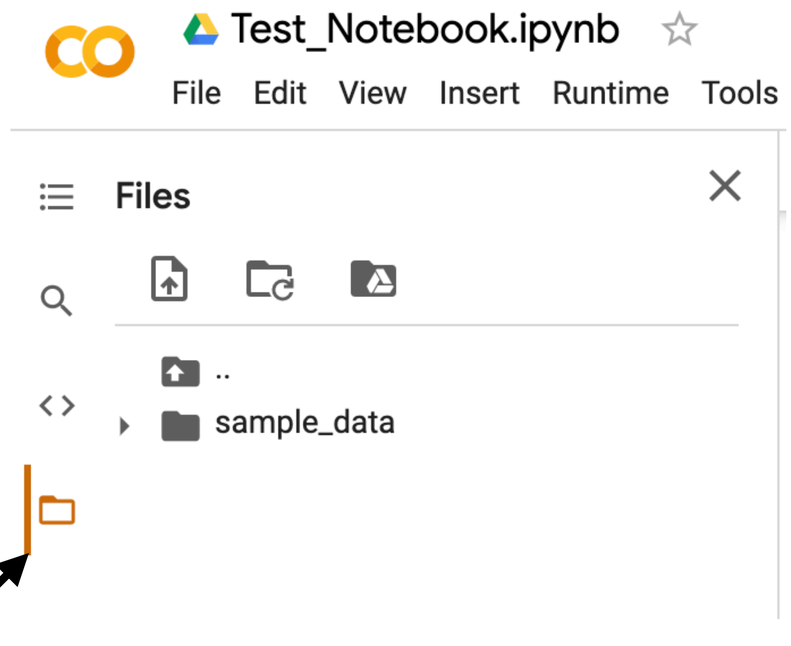
Path in Google Drive:
a string containing the file name, preceded by its folders and separated by /

```
filepath = 'drive/My Drive/Data_folder/Seattle_tides.txt'
```

These are the folders where you put your data file in your Google Drive

Alternatively, you can use the Colab user interface to mount your drive.

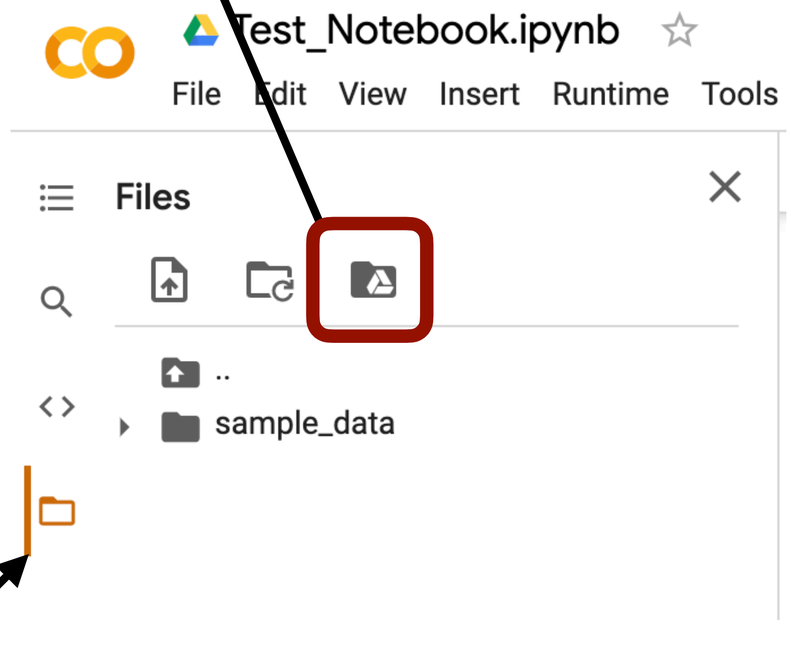
Mount your Google Drive to Colab (User Interface - UI)

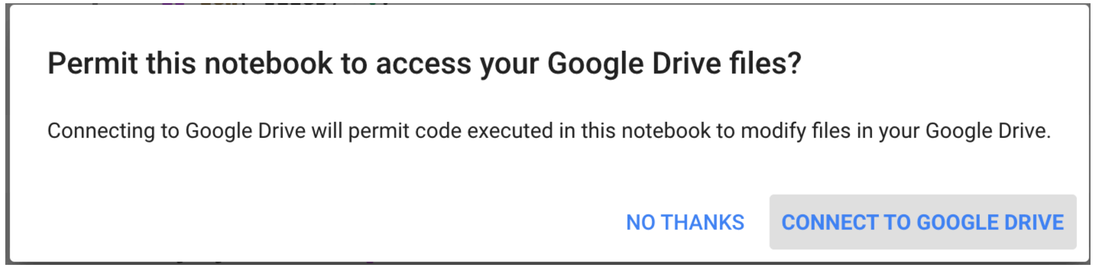


This is the sidebar menu for managing files

Mount your Google Drive to Colab (User Interface - UI)

Click here for a pop-up to open

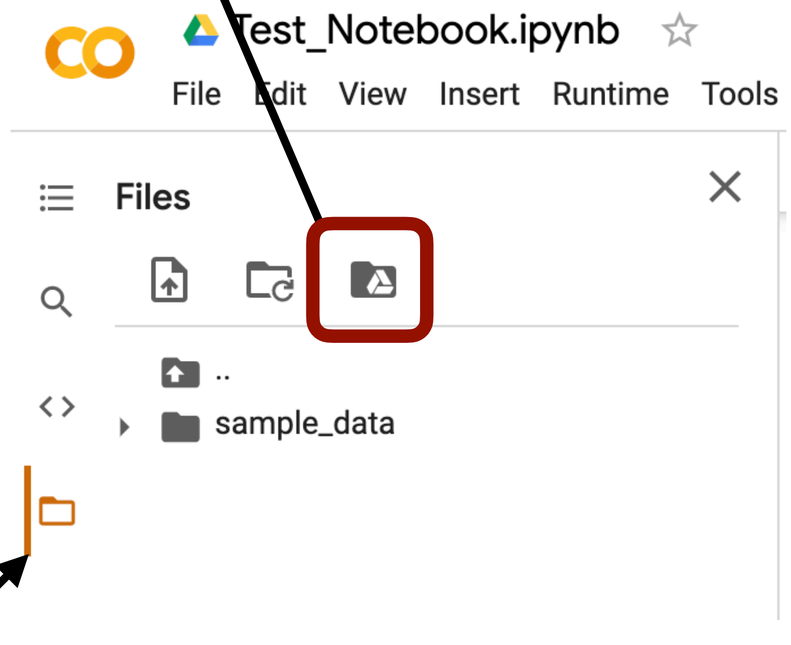




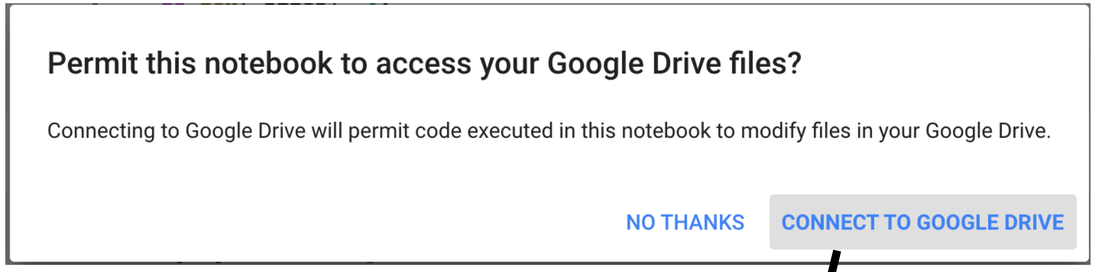
This is the sidebar menu for managing files

Mount your Google Drive to Colab (User Interface - UI)

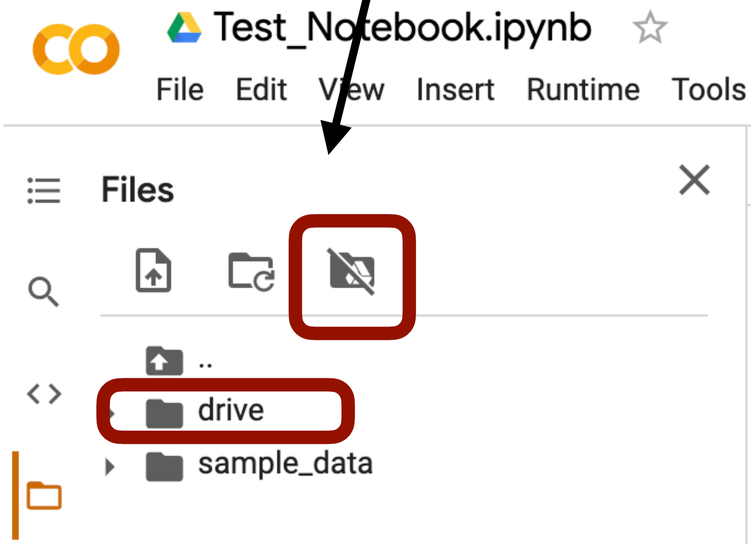
Click here for a pop-up to open



This is the sidebar menu for managing files



This method only works if you are the only editor on a notebook, but doing it this way means you don't have to re-mount Google Drive every runtime



Instead of accessing data on your mounted drive, you can manually upload individual files to your colab notebook.

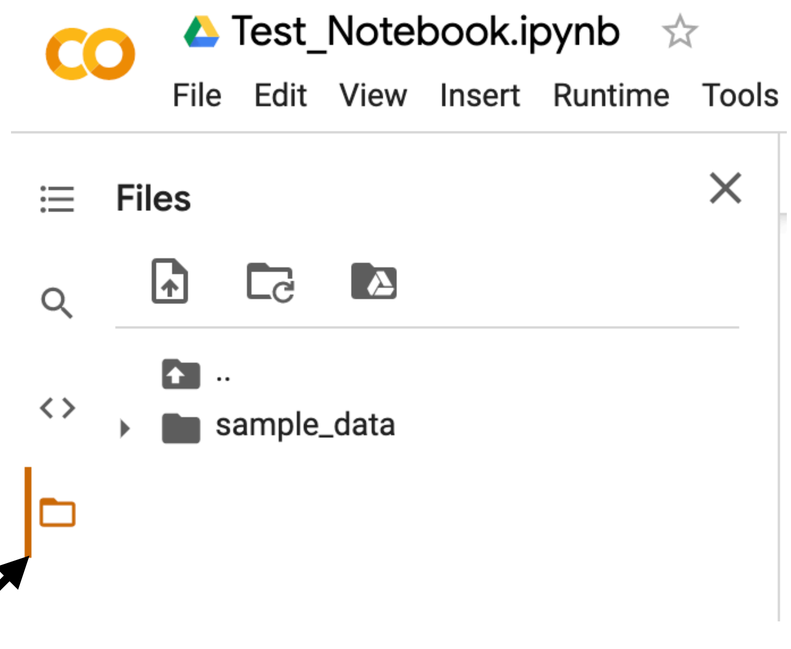
Uploading local files every runtime

User Interface (UI)

In coding cells

Uploading local files every runtime

User Interface (UI)



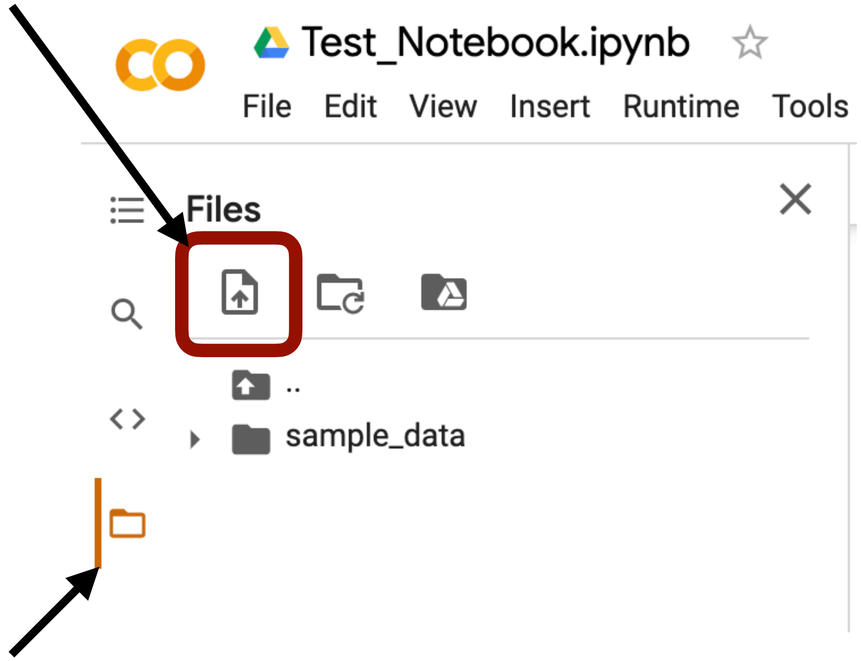
This is the sidebar menu for managing files

In coding cells

Uploading local files every runtime

User Interface (UI)

Click here and select the file
(or files, using ctrl/⌘ + click)



This is the sidebar menu
for managing files

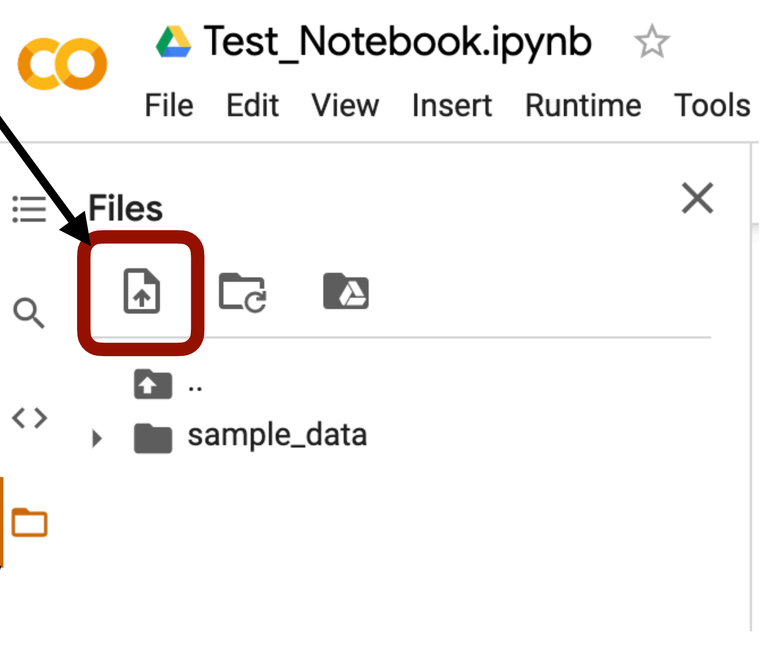
Uploading local files every runtime

User Interface (UI)

Click here and select the file
(or files, using ctrl/⌘ + click)



This is the sidebar menu
for managing files

In coding cells

```
1 from google.colab import files
2 uploaded = files.upload()
3
4
```

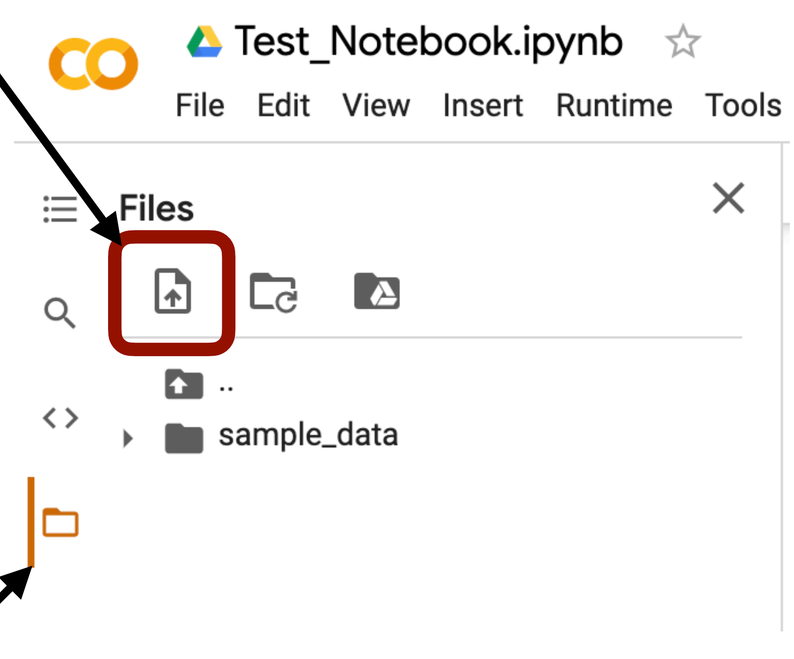
Choose Files | No file chosen | Cancel upload

Click here and select the files
(or files, using ctrl/⌘ + click)

Uploading local files every runtime

User Interface (UI)

Click here and select the file (or files, using ctrl/⌘ + click)



This is the sidebar menu for managing files

In coding cells

```
1 from google.colab import files
2 uploaded = files.upload()
3
4
```

Optional

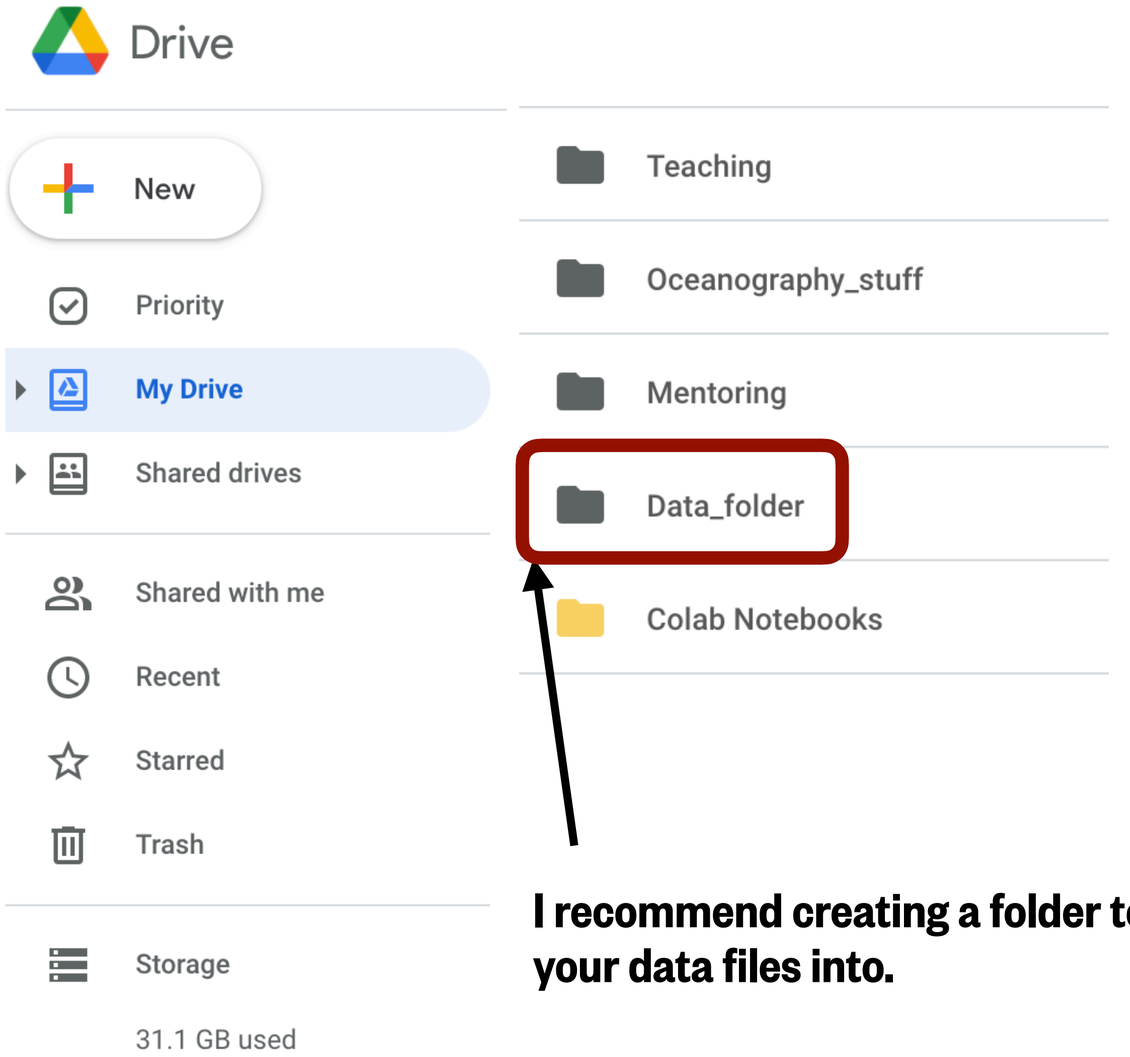
Click here and select the files (or files, using ctrl/⌘ + click)

The output of this is a Python dictionary, with each file name as a key and the file contents as its corresponding value.

Both of these options require you to manually select the files!

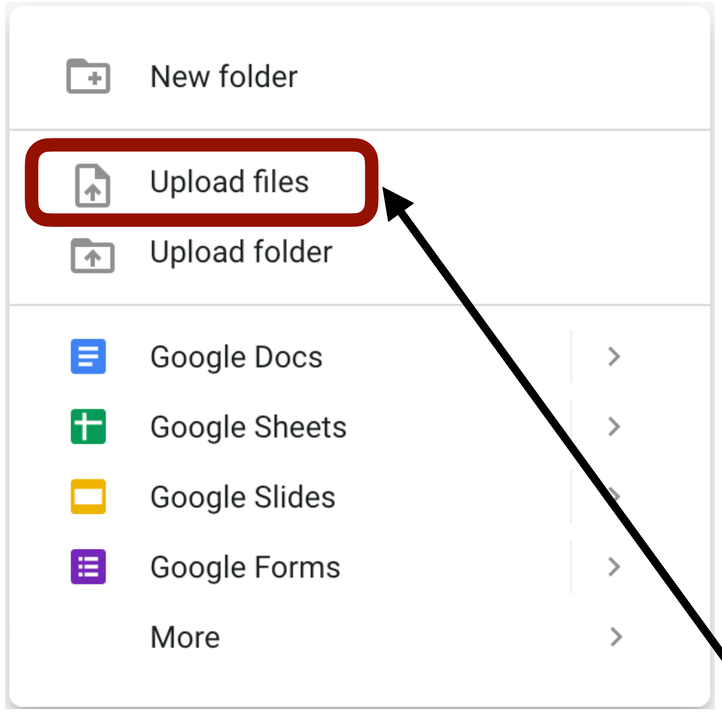
Using Google Drive - uploading your files

drive.google.com



I recommend creating a folder to put your data files into.

Right click to get this menu



Click here and select the file (or files, using ctrl/⌘ + click)

What we'll cover in this lesson

1. Loading and saving files to Google Colab

2. **Loading data using readlines and numpy**

Sample data - Seattle tidal record

2
3 file_obj = open(filepath, 'r')
4
```

Using **open** does not read the file. Instead, it creates a file object that can be read later. Think of it like opening a book...

readlines( )

To read the file after opening, use the function **readlines( )**

```
1 filepath = 'drive/My Drive/Data_folder/Seattle_tides_predicted_20201001_20201024.txt'
2
3 file_obj = open(filepath, 'r')
4
5 lines = file_obj.readlines()
```

This function loads the entire file into memory and will return a list object containing each of the lines in your file as items.

readlines( )

To read the file after opening, use the function **readlines( )**

```
1 filepath = 'drive/My Drive/Data_folder/Seattle_tides_predicted_20201001_20201024.txt'
2
3 file_obj = open(filepath, 'r')
4
5 lines = file_obj.readlines()
6
7 file_obj.close()
8
9 print(lines)
10 print(len(lines))
11
```

When you are done reading the file, you have to close it.

```
['NOAA/NOS/CO-OPS\n', 'Disclaimer: These data are based upon the latest information availa
5774
```

When you print the list, it is not very easy to look at.
The **len( )** function gives you the total number of lines.

readlines( )

To read the file after opening, use the function **readlines( )**

```
1 filepath = 'drive/My Drive/Data_folder/Seattle_tides_predicted_20201001_20201024.txt'
2
3 file_obj = open(filepath, 'r')
4
5 lines = file_obj.readlines()
6
7 file_obj.close()
8
9 print(lines)
10 print(len(lines))
11
```

```
['NOAA/NOS/CO-OPS\n', 'Disclaimer: These data are based upon the latest information available as of the date of your request, and may differ from the publis
5774
```

The **len( )** function gives you the total number of lines.
When you print the list, it is not very easy to look at. Plus, loading files that are large can cause your code to slow down.

readline( )

Instead of reading the whole file at once with **readlines( )**, read each line as you go using **readline( )** and a for loop.

```
1 filepath = 'drive/My Drive/Data_folder/Seattle_tides_predicted_20201001_20201024.txt'
2
3 file_obj = open(filepath, 'r')
4
5 for i in range(30):
6   line = file_obj.readline()
7   print(line)
8
9 file_obj.close()
10
```

The **readline( )** function reads the next line in the file every time that it is run, so looping 30 times will print the first 30 lines.

readline( )

Header

```
NOAA/NOS/CO-OPS

Disclaimer: These data are based upon the latest information

Daily Tide Predictions

StationName: Seattle

State: WA

Stationid: 9447130

2020/10/01      Thu     01:30   -0.62
```

Here is what we know about our file now:

1) Our file path on the Google Drive
2) There are 14 lines of header information
    - Station, state, units, interval/frequency
3) Columns 0, 1, 2 are date information
4) Column 3 has floats
5) The columns are separated by white space

Extracting the data

Now that we know what the file structure is, we can load the data using the numpy function, **np.genfromtxt( )**

This function takes a file and puts its data elements into a numpy array. We have to carefully consider the file structure to properly load the data.

```
1 import numpy as np
2 filepath = 'data/My Drive/Data_folder/Seattle_tides_predicted_20201001_20201024.txt'
3
4 data = np.genfromtxt(…)
5
```

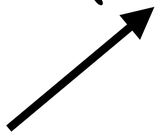
We start building our arguments for loading our data.

Here is what we know about our file now:

1) Our file path on the Google Drive
2) There are 14 lines of header information
    - Station, state, units, interval/frequency
3) Columns 0, 1, 2 are date information
4) Column 3 has floats
5) The columns are separated by white space

np.genfromtxt( )

```
data = np.genfromtxt(…)
```



Here is what we know about our file now:

1) Our file path on the Google Drive

2) There are 14 lines of header information

   - Station, state, units, interval/frequency

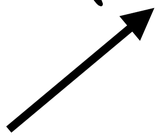
3) Columns 0, 1, 2 are date information

4) Column 3 has floats

5) The columns are separated by white space

np.genfromtxt( )

```
data = np.genfromtxt(…)
```



```
       filepath
```

Here is what we know about our file now:

1) Our file path on the Google Drive

2) There are 14 lines of header information

   - Station, state, units, interval/frequency

3) Columns 0, 1, 2 are date information

4) Column 3 has floats

5) The columns are separated by white space

np.genfromtxt( )

```
data = np.genfromtxt(…)

        filepath

    skip_header = 14
```

Here is what we know about our file now:

1) Our file path on the Google Drive
2) There are 14 lines of header information
    - Station, state, units, interval/frequency
3) Columns 0, 1, 2 are date information
4) Column 3 has floats
5) The columns are separated by white space

np.genfromtxt( )

```
data = np.genfromtxt(…)

        filepath
    skip_header = 14
      usecols = 3
    dtype = float
```

Here is what we know about our file now:

1) Our file path on the Google Drive
2) There are 14 lines of header information
    - Station, state, units, interval/frequency
3) Columns 0, 1, 2 are date information
4) Column 3 has floats
5) The columns are separated by white space

np.genfromtxt( )

```
data = np.genfromtxt(…)

        filepath
     skip_header = 14
        usecols = 3
       dtype = float
  (delimiter = None)
```

Here is what we know about our file now:

1) Our file path on the Google Drive
2) There are 14 lines of header information
   - Station, state, units, interval/frequency
3) Columns 0, 1, 2 are date information
4) Column 3 has floats
5) The columns are separated by white space

np.genfromtxt( )

```
data_time = np.genfromtxt(…)
```

```
filepath
skip_header = 14
usecols = (0,1,2)
dtype = str
(delimiter = None)
```

Here is what we know about our file now:

1) Our file path on the Google Drive
2) There are 14 lines of header information
   - Station, state, units, interval/frequency
3) Columns 0, 1, 2 are date information
4) Column 3 has floats
5) The columns are separated by white space

np.genfromtxt( )

```python
import numpy as np
filepath = 'drive/My Drive/Data_folder/Seattle_tides_predicted_20201001_20201024.txt'

data = np.genfromtxt(filepath,skip_header=14,dtype=float,usecols=3,delimiter=None)
data_time = np.genfromtxt(filepath,skip_header=14,dtype=str,usecols=(0,1,2),delimiter=None)

print('Length:',len(data))
print(data)
print()
print('Length:',len(data_time))
print(data_time)

```

```
Length: 5760
[-1.12 -1.1  -1.08 ...  0.35  0.36  0.37]

Length: 5760
[['2020/10/01' 'Thu' '00:00']
 ['2020/10/01' 'Thu' '00:06']
 ['2020/10/01' 'Thu' '00:12']
 ...
 ['2020/10/24' 'Sat' '23:42']
 ['2020/10/24' 'Sat' '23:48']
 ['2020/10/24' 'Sat' '23:54']]
```

We have successfully loaded data!

Formatting function arguments

numpy.genfromtxt

numpy.genfromtxt(*fname*, *dtype=<class 'float'>*, *comments='#'*, *delimiter=None*, *skip_header=0*, *skip_footer=0*, *converters=None*, *missing_values=None*, *filling_values=None*, *usecols=None*, *names=None*, *excludelist=None*, *deletechars=" !#$%&'()*+, -./:;<=>?@[\]^{|}~"*, *replace_space='_'*, *autostrip=False*, *case_sensitive=True*, *defaultfmt='f%i'*, *unpack=None*, *usemask=False*, *loose=True*, *invalid_raise=True*, *max_rows=None*, *encoding='bytes'*) [source]

From the official numpy documentation online

https://numpy.org/doc/stable/reference/generated/numpy.genfromtxt.html

Parameters:

fname : *file, str, pathlib.Path, list of str, generator*
File, filename, list, or generator to read. If the filename extension is *gz* or bz2, the file is first decompressed. Note that generators must return byte strings. The strings in a list or produced by a generator are treated as lines.

dtype : *dtype, optional*
Data type of the resulting array. If None, the dtypes will be determined by the contents of each column, individually.

comments : *str, optional*
The character used to indicate the start of a comment. All the characters occurring on a line after a comment are discarded

delimiter : *str, int, or sequence, optional*
The string used to separate values. By default, any consecutive whitespaces act as delimiter. An integer or sequence of integers can also be provided as width(s) of each field.

skiprows : *int, optional*
skiprows was removed in numpy 1.10. Please use *skip_header* instead.

skip_header : *int, optional*
The number of lines to skip at the beginning of the file.

skip_footer : *int, optional*
The number of lines to skip at the end of the file.

converters : *variable, optional*
The set of functions that convert the data of a column to a value. The converters can also be used to provide a default value for missing data: `converters = {3: lambda s: float(s or 0)}`.

missing : *variable, optional*
missing was removed in numpy 1.10. Please use *missing_values* instead.

missing_values : *variable, optional*
The set of strings corresponding to missing data.

filling_values : *variable, optional*
The set of values to be used as default when the data are missing.

usecols : *sequence, optional*
Which columns to read, with 0 being the first. For example, `usecols = (1, 4, 5)` will extract the 2nd, 5th and 6th columns.

names : *{None, True, str, sequence}, optional*
If *names* is True, the field names are read from the first line after the first *skip_header* lines. This line can optionally be proceeded by a comment delimiter. If *names* is a sequence or a single-string of comma-separated names, the names will be used to define the field names in a structured dtype. If *names* is None, the names of the dtype fields will be used, if any.

excludelist : *sequence, optional*
A list of names to exclude. This list is appended to the default list ['return','file','print']. Excluded names are appended an underscore: for example, *file* would become *file_*.

deletechars : *str, optional*
A string combining invalid characters that must be deleted from the names.

defaultfmt : *str, optional*
A format used to define default field names, such as "f%i" or "f_%02i".

autostrip : *bool, optional*
Whether to automatically strip white spaces from the variables.

replace_space : *char, optional*
Character(s) used in replacement of white spaces in the variables names. By default, use a '_'.

case_sensitive : *{True, False, 'upper', 'lower'}, optional*
If True, field names are case sensitive. If False or 'upper', field names are converted to upper case. If 'lower', field names are converted to lower case.

unpack : *bool, optional*
If True, the returned array is transposed, so that arguments may be unpacked using `x, y, z = loadtxt(...)`

usemask : *bool, optional*
If True, return a masked array. If False, return a regular array.

loose : *bool, optional*
If True, do not raise errors for invalid values.
